Program Synthesis with Noise (ALG)

```
Input: Dataset \mathcal{D}, initial (e.g. random) dataset \emptyset \subset d_1 \subseteq \mathcal{D}
    Output: Program p
 1 begin
      progs \leftarrow \emptyset
 2
      i \leftarrow 0
 3
       repeat
 4
          i \leftarrow i + 1
 5
          // Dataset sampling step
 6
          if i > 1 then
 7
           | d_i \leftarrow ds(progs, |d_{i-1}| + 1)
 8
           end
 9
           // Program generation step
10
          p_i \leftarrow gen(d_i)
11
          if found_program(p<sub>i</sub>) then
12
              return p_i
13
          end
14
          progs \leftarrow progs \cup \{p_i\}
15
       until d_i = \mathcal{D};
16
       return "No such program exists"
17
18 end
```

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

Basic Info

Definition (HDS)

A hard dataset sampler is a function ds^H such that for $Q \subseteq P$, $d' = ds^H(Q, min_size)$, it holds that $\forall p \in Q.r(\mathcal{D}, p) \leq r(d', p)$ and $|d'| \geq min_size$.

Theorem (THM)

Let $Q = \{p_1, ..., p_{i-1}\}$ be the set of programs generated up to iteration *i* of Algorithm ALG, where the dataset sampler ds satisfies Definition HDS. If $\varepsilon \ge r(d_i, p_{best}) - r(\mathcal{D}, p_{best})$, then $p_i = gen(d_i) \notin Q'$, where

$$Q' = \{ p \in Q \mid r(\mathcal{D}, p) > r(\mathcal{D}, p_{best}) + \varepsilon \}.$$

Noise Bound

Definition (NB)

We say that ε_k is a **noise bound** for samples of size k if for the program p_{best} : $\forall d \subseteq \mathcal{D}. |d| = k \Longrightarrow \varepsilon_k \ge r(d, p_{best}) - r(\mathcal{D}, p_{best})$, where r is a risk function (e.g. error rate, the number of error etc.)

Remark: We can easily instantiate THM by setting $\varepsilon = \varepsilon_k$ (see the precondition of THM " $\varepsilon \ge r(d_i, p_{best}) - r(\mathcal{D}, p_{best})$ ").

Program Synthesis with Noise (ALG)

Termination criterion

Input: Dataset \mathcal{D} , initial (e.g. random) dataset $\emptyset \subset d_1 \subseteq \mathcal{D}$ **Output**: Program p

1 begin

| 2 | $progs \leftarrow \emptyset$ |
|---------|---|
| 3 | $i \leftarrow 0$ |
| 4 | repeat |
| 5 | $i \leftarrow i+1$ |
| 6 | // Dataset sampling step |
| 7 | if $i > 1$ then |
| 8 | $ d_i \leftarrow ds(progs, d_{i-1} + 1)$ |
| 9 | end |
| 10 | // Program generation step |
| 11 | $p_i \leftarrow gen(d_i)$ |
| 12 | if found_program (p_i) then |
| 13 | return p_i |
| 14 | end |
| 15 | $progs \leftarrow progs \cup \{p_i\}$ |
| 16 | until $d_i = \mathcal{D}$; |
| 17 | return "No such program exists" |
| , 18 | end |

Termination criteria

We limit the error rate for a satisfactory program

$$r(\mathcal{D}, p_{\mathsf{satisfactory}}) \leq r(\mathcal{D}, p_{\mathsf{best}}) + \varepsilon_{\mathsf{satisfactory}}.$$

The stopping criteria has a form:

$$found_program(p_i) \triangleq (p_i \in progs) \land \varepsilon_{|d_i|} \le \varepsilon_{satisfactory}$$

By Definition NB $r(d, p_{best}) - r(D, p_{best}) \le \varepsilon_{|d_i|}$ (that is the precondition of THM), thus $p_i = gen(d_i) \notin Q'$, where $Q' = \{p \in progs \mid r(D, p) > r(D, p_{best}) + \varepsilon_{|d_i|}\}$. Since all the members of Q satisfies THM (due to the noise bound), if $p_i \in progs$ it satisfies the following condition:

$$r(\mathcal{D}, p_i) \leq r(\mathcal{D}, p_{best}) + \varepsilon_i.$$

Termination criterion

Special case: bound on the number of errors

Let us assume that p_{best} makes at most K errors on D. Consider following the cost function

$$r_{K}(d, p) = min(num_errors(d, p), K + 1).$$

By Definition NB, $\varepsilon_k = 0$. By setting $\varepsilon_{satisfactory} = 0$ we get the following sopping criteria:

found_program
$$(p_i) \triangleq (p_i \in progs).$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Thus, the Algorithm ALG terminates with p_{best} .

BitSyn: bitstream programs from noisy data

Scenarios to consider:

- 1. the dataset \mathcal{D} is obtained dynamically and the noise is bounded (i.e., up to K errors);
- 2. the dataset \mathcal{D} is present in advance and may contain an unknown number of errors.

Goal: synthesize a program having input/output examples (32-bit integers).

Key feature: a generated program may not satisfy all provided input/output examples.

Key components of BitSyn

Objective. Tackle with overfitting problem

Regularization with function $\Omega(p_a) : \mathbb{P} \to \mathbb{R}^+$ that outputs the number of the used instructions.

Regularized objective:

$$r_{reg}(d, p) = \operatorname{error_rate}(d, p) + \lambda \cdot \Omega(p),$$

where $\lambda \in \mathbb{R}$ is a regularization constant.

Example

Given data:

 $\textit{d}_{1} = \left\{ \left\{ 2 \rightarrow 3 \right\}, \left\{ 5 \rightarrow 6 \right\}, \left\{ 10 \rightarrow 11 \right\}, \left\{ 15 \rightarrow 16 \right\}, \left\{ -2 \rightarrow 0 \right\} \right\}$

True function: $p_a = \text{return}$ input + 1, satisfies all the examples except for $\{-2 \rightarrow 0\}$.

Learned function: $p_a = \text{return input} + 1 + (\text{input} >> 7).$

Key components of BitSyn Z3 SMT Solver. Scheme

Figure: The scheme of Z3 SMT Solver, see more details on http://research.microsoft.com/projects/z3

Data Format

Input for SML solver:

- Encoded set of input/output examples $d = \{x_i\}_{i=1}^n {}^2$
- ▶ Number of allowed errors T, the solution must satisfy formula $T \ge \sum_{i=1}^{n} [$ if χ_i then 0 else 1]

The program looks for the best scoring solution by iterating over the lengths of programs and T.

Case 1: Examples in D are provided dynamically

Questions to answer

- How many errors can be processed to synthesize a correct solution?
- How many (more) examples does BitSyn need in order to compensate for the incorrect examples?

Case 1: Examples in D are provided dynamically $_{\mbox{\scriptsize Results}}$

Case 2: All examples in D are given in advance

Questions to answer

Are the unsatisfied examples exactly the incorrect ones?

Remark: in the experiments the generated programs are not available before the process of anomaly detection starts. The found unsatisfied examples is assumed to be outliers.

Case 2: All examples in D are given in advance Results

Figure: Ability of BitSyn to detect an incorrect example for programs (P1-P9) depending on total number of examples and regularization constant λ .

The results show that we need a dataset with more than 10 examples and a regularization constant between 0.05 and 0.1.

Related work

Boolean program synthesis

- synthesis from examples;
- partial programs;

one part of a program is given imperatively and the other is given declaratively (e.g. conditions need to be achieved or maintained).

synchronization.

All these approaches attempt to satisfy **all** provided examples and constraints.

Quantitative program synthesis

 Goal is to synthesize a program satisfying weaker specification and maximizing some quantitative objective

Summary

- A program synthesis approach that can deal with incorrect examples;
- Returns an optimal (or almost optimal) program and terminates early in case of the known bound on the cost function for the best program.
- Some suboptimal candidate programs are removed from the search space if the bound is unknown.
